k-Nearest Neighbor (kNN) exercise

The kNN classifier consists of two stages:

- During training, the classifier takes the training data and simply remembers it
- During testing, kNN classifies every test image by comparing to all training images and transfering the labels of the k most similar training examples
- · The value of k is cross-validated

In this exercise you will implement these steps and understand the basic Image Classification pipeline, cross-validation, and gain proficiency in writing efficient, vectorized code.

```
# Run some setup code for this notebook.
 1
 2
 3 import random
 4 import numpy as np
 5 from cs175.data_utils import load_CIFAR10
   import matplotlib.pyplot as plt
 7
   #from future import print function
9
10 | # This is a bit of magic to make matplotlib figures appear inline in the notebook
11 # rather than in a new window.
   %matplotlib inline
   plt.rcParams['figure.figsize'] = (10.0, 8.0) # set default size of plots
   plt.rcParams['image.interpolation'] = 'nearest'
   plt.rcParams['image.cmap'] = 'gray'
15
16
17 # Some more magic so that the notebook will reload external python modules;
18 | # see http://stackoverflow.com/questions/1907993/autoreload-of-modules-in-ipython
19 %load ext autoreload
20 %autoreload 2
```

In [2]:

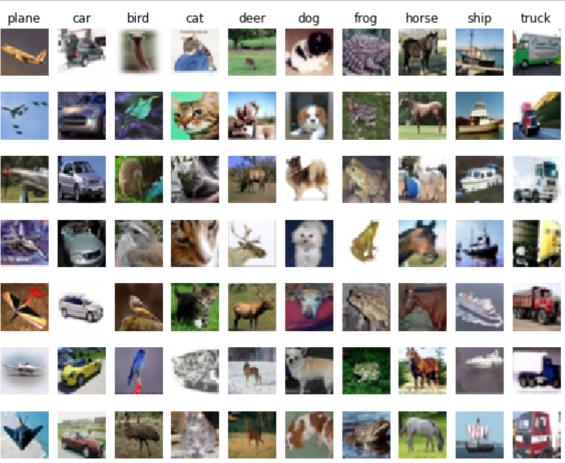

```
# Load the raw CIFAR-10 data.
cifar10_dir = 'cs175/datasets/cifar-10-batches-py'
X_train, y_train, X_test, y_test = load_CIFAR10(cifar10_dir)

# As a sanity check, we print out the size of the training and test data.
print('Training data shape: ', X_train.shape)
print('Training labels shape: ', y_train.shape)
print('Test data shape: ', X_test.shape)
print('Test labels shape: ', y_test.shape)
```

```
Training data shape: (50000, 32, 32, 3)
Training labels shape: (50000,)
Test data shape: (10000, 32, 32, 3)
Test labels shape: (10000,)
```

```
In [3]:
```

```
# Visualize some examples from the dataset.
   # We show a few examples of training images from each class.
   classes = ['plane', 'car', 'bird', 'cat', 'deer', 'dog', 'frog', 'horse', 'ship', 'truck']
   num_classes = len(classes)
   samples_per_class = 7
 5
   for y, cls in enumerate(classes):
 6
 7
       idxs = np. flatnonzero(y_train == y)
       idxs = np.random.choice(idxs, samples_per_class, replace=False)
 8
 9
       for i, idx in enumerate(idxs):
10
            plt idx = i * num classes + y + 1
           plt.subplot(samples_per_class, num_classes, plt_idx)
11
12
           plt.imshow(X_train[idx].astype('uint8'))
13
            plt.axis('off')
            if i == 0:
14
15
                plt.title(cls)
16
   plt. show()
```

In [4]:

```
# Subsample the data for more efficient code execution in this exercise
num_training = 5000
mask = list(range(num_training))

X_train = X_train[mask]
y_train = y_train[mask]

num_test = 500
mask = list(range(num_test))
X_test = X_test[mask]

y_test = y_test[mask]
```

In [5]:

```
# Reshape the image data into rows
X_train = np.reshape(X_train, (X_train.shape[0], -1))
X_test = np.reshape(X_test, (X_test.shape[0], -1))
print(X_train.shape, X_test.shape)
```

(5000, 3072) (500, 3072)

In [6]:

```
from cs175.classifiers import KNearestNeighbor

treate a kNN classifier instance.

Remember that training a kNN classifier is a noop:

the Classifier simply remembers the data and does no further processing classifier = KNearestNeighbor()

classifier.train(X_train, y_train)
```

We would now like to classify the test data with the kNN classifier. Recall that we can break down this process into two steps:

- 1. First we must compute the distances between all test examples and all train examples.
- 2. Given these distances, for each test example we find the k nearest examples and have them vote for the label

Lets begin with computing the distance matrix between all training and test examples. For example, if there are **Ntr** training examples and **Nte** test examples, this stage should result in a **Nte x Ntr** matrix where each element (i,j) is the distance between the i-th test and j-th train example.

First, open cs175/classifiers/k_nearest_neighbor.py and implement the function compute_distances_two_loops that uses a (very inefficient) double loop over all pairs of (test, train) examples and computes the distance matrix one element at a time.

In [7]:

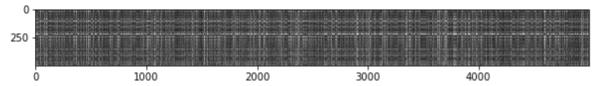

```
# Open cs175/classifiers/k_nearest_neighbor.py and implement
# compute_distances_two_loops.

# Test your implementation:
dists = classifier.compute_distances_two_loops(X_test)
print(dists.shape)
```

(500, 5000)

In [8]:

```
# We can visualize the distance matrix: each row is a single test example and
# its distances to training examples
plt.imshow(dists, interpolation='none')
plt.show()
```

Inline Question #1: Notice the structured patterns in the distance matrix, where some rows or columns are visible brighter. (Note that with the default color scheme black indicates low distances while white indicates high distances.)

- · What in the data is the cause behind the distinctly bright rows?
- · What causes the columns?

Your Answer: *fill this in.* bright rows shows when some data in the test images has large distance(not similar) away from training images, therefore the large distance is shown by bright rows.

colums represents the training images has large distance(not similar) away from test images.

In [9]:

```
# Now implement the function predict_labels and run the code below:
# We use k = 1 (which is Nearest Neighbor).

y_test_pred = classifier.predict_labels(dists, k=1)

# Compute and print the fraction of correctly predicted examples
num_correct = np. sum(y_test_pred == y_test)
accuracy = float(num_correct) / num_test
print('Got %d / %d correct => accuracy: %f' % (num_correct, num_test, accuracy))
```

Got 137 / 500 correct => accuracy: 0.274000

You should expect to see approximately 27% accuracy. Now lets try out a larger k, say k=5:

In [10]:

```
1  y_test_pred = classifier.predict_labels(dists, k=5)
2  num_correct = np.sum(y_test_pred == y_test)
3  accuracy = float(num_correct) / num_test
4  print('Got %d / %d correct => accuracy: %f' % (num_correct, num_test, accuracy))
```

Got 139 / 500 correct => accuracy: 0.278000

You should expect to see a slightly better performance than with $\ k=1$.

In [11]:

```
# Now lets speed up distance matrix computation by using partial vectorization
   # with one loop. Implement the function compute_distances_one_loop and run the
 3 # code below:
   dists one = classifier.compute distances one loop(X test)
 5
   # To ensure that our vectorized implementation is correct, we make sure that it
 7
   # agrees with the naive implementation. There are many ways to decide whether
   # two matrices are similar; one of the simplest is the Frobenius norm. In case
 9
   # you haven't seen it before, the Frobenius norm of two matrices is the square
10 | # root of the squared sum of differences of all elements; in other words, reshape
11 # the matrices into vectors and compute the Euclidean distance between them.
   difference = np. linalg. norm(dists - dists_one, ord='fro')
   print('Difference was: %f' % (difference, ))
   if difference < 0.001:
14
       print('Good! The distance matrices are the same')
15
16
   else:
17
       print('Uh-oh! The distance matrices are different')
```

Difference was: 0.000000

Good! The distance matrices are the same

In [12]:

```
# Now implement the fully vectorized version inside compute_distances_no_loops
 1
   # and run the code
   dists two = classifier.compute distances no loops(X test)
   # check that the distance matrix agrees with the one we computed before:
 5
   difference = np. linalg. norm(dists - dists two, ord='fro')
   print('Difference was: %f' % (difference, ))
 7
   if difference < 0.001:
 8
       print('Good! The distance matrices are the same')
 9
10
   else:
        print('Uh-oh! The distance matrices are different')
11
```

Difference was: 0.000000

Good! The distance matrices are the same

In [13]:

```
# Let's compare how fast the implementations are
 2
   def time_function(f, *args):
 3
 4
       Call a function f with args and return the time (in seconds) that it took to execute.
 5
 6
        import time
 7
        tic = time.time()
 8
        f (*args)
 9
        toc = time.time()
10
       return toc - tic
11
    two loop time = time function(classifier.compute distances two loops, X test)
12
    print('Two loop version took %f seconds' % two_loop_time)
13
14
   one_loop_time = time_function(classifier.compute_distances_one_loop, X_test)
15
    print('One loop version took %f seconds' % one_loop_time)
16
17
18
   no_loop_time = time_function(classifier.compute_distances_no_loops, X_test)
   print('No loop version took %f seconds' % no_loop_time)
19
20
21
   # you should see significantly faster performance with the fully vectorized implementation
```

Two loop version took 24.351843 seconds One loop version took 42.500599 seconds No loop version took 0.159026 seconds

Cross-validation

We have implemented the k-Nearest Neighbor classifier but we set the value k = 5 arbitrarily. We will now determine the best value of this hyperparameter with cross-validation.

```
In [14]:
```

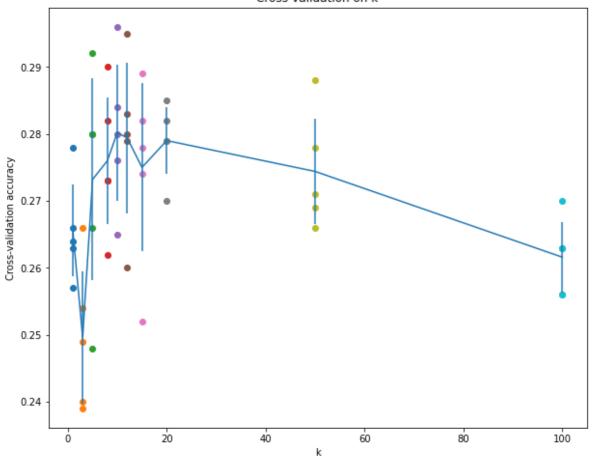

```
num folds = 5
1
2
  k_{\text{choices}} = [1, 3, 5, 8, 10, 12, 15, 20, 50, 100]
3
4
  X train folds = []
5
  v train folds = []
  6
7
                                                               #
8
  # Split up the training data into folds. After splitting, X_train_folds and
9
  # y_train_folds should each be lists of length num_folds, where
  # y train folds[i] is the label vector for the points in X train folds[i].
10
11
  # Hint: Look up the numpy array split function.
  12
13
  X_train_folds = np. array_split(X_train, num_folds)
  y train folds = np. array split(y train, num folds)
  15
16
                            END OF YOUR CODE
  17
18
19
  # A dictionary holding the accuracies for different values of k that we find
  # when running cross-validation. After running cross-validation,
20
21
  # k_to_accuracies[k] should be a list of length num_folds giving the different
22
  # accuracy values that we found when using that value of k.
